Homework #(HW7) Seo Junwon

INSTRUCTIONS

- Anything that is received after the deadline will be considered to be late and we do not receive late homeworks. We do however ignore your lowest homework grade.
- Answers to every theory questions need to be submitted electronically on ETL. Only PDF generated from LaTex is accepted.
- Make sure you prepare the answers to each question separately. This helps us dispatch the problems to different graders.
- Collaboration on solving the homework is allowed. Discussions are encouraged but you should think about the problems on your own.
- If you do collaborate with someone or use a book or website, you are expected to write up your solution independently. That is, close the book and all of your notes before starting to write up your solution.

1 Getting familiar with KL Divergence

Theorem 1. *if p follows* $N(\mu, \Sigma)$, $Pr(p = x) = \frac{e^{-0.5(x-\mu)^T \Sigma^{-1}(x-\mu)}}{2\pi^{n/2} det(\Sigma)^{0.5}}$

 $= 0.5* (log \frac{\det \Sigma_2}{\det \Sigma_2} - n + tr(\Sigma_2^{-1}\Sigma_1) + (\mu_2 - \mu_1)^T \Sigma_2^{-1} (\mu_2 - \mu_1))$

$$\begin{split} &D(p\|q)\\ &=E_p[log p-log q]\\ &=0.5*E_p[-log \det \Sigma_1-(x-\mu_1)^T\Sigma_{-1}(x-\mu_1)+log \det \Sigma_2+(x-\mu_1)^T\Sigma_{-1}(x-\mu_1)]\\ &=0.5*(log \frac{\det \Sigma_2}{\det \Sigma_2}+E_p[-tr(\Sigma_1^{-1}(x-\mu_1)(x-\mu_1)^T)+tr(\Sigma_2^{-1}(x-\mu_2)(x-\mu_2)^T)])\\ &=0.5*(log \frac{\det \Sigma_2}{\det \Sigma_2}-n+E_p[tr(\Sigma_2^{-1}(x-\mu_2)(x-\mu_2)^T)])\\ &=0.5*(log \frac{\det \Sigma_2}{\det \Sigma_2}-n+tr(\Sigma_2^{-1}(\Sigma_1+(\mu_1\mu_1^T)-2\mu_2\mu_1^T+\mu_2(\mu_2)^T))) \end{split}$$

Homework #(HW7) Seo Junwon

2 Forward and Reverse KL Divergence

2.1 Forward KL

```
\begin{split} \theta^* &= argmin_\theta D_{KL}(p(x) \| q_\theta(x) \\ &= argmin_\theta E_p[log(p(x)) - log(q(x))] \\ &= argmin_\theta E_p[-log(q(x))] - H(p(x)) \\ &= argmin_\theta E_p[-log(q(x))] \text{ , since p is fixed distribution.} \end{split}
```

2.2 Reverse KL

$$\theta^* = argmin_{\theta} D_{KL}(q_{\theta}(x) || p(x))$$

$$= argmin_{\theta} E_q[-log(p(x)) + log(q(x))]$$

$$= argmin_{\theta} E_q[-log(q(x))] - H(q(x))$$

2.3 Meaning

 $E_p[-log(q(x))]$ and $E_q[-log(p(x))]$ is log - likelyhood between p and q.

Whenever P has hight probability, Q must also have high probability. We consider this mean-seeking behavior in Forward KL, and Mode-seeking behavior in reverse KL.

$$H(q(x))$$
 is Entropy of q.

When p is a unimodal Gaussian, q_{θ} will follow same Gaussian distribution with same parameter.

When P is a bimodal Gaussian, The forward KL q will approximate distribution centers itself between the two modes, so that it can have high coverage of both. The forward KL divergence does not penalize Q for having high probability mass where P does not.

Homework #(HW7) Seo Junwon

However, in reverse KL, q will approximate distribution within a mode of P since it's required that sample from q have high probability under P. The entropy term prevents the approximate distribution collapsing to non mode.

3 Mutual Information and independence

3.1 1

$$\begin{split} I(X;Y) &= D_{KL}(p(X,Y) \| p(X)p(Y)) \\ &= E_{X,Y}(log\frac{p(X,Y)}{p(X)p(Y)}) \\ \text{As X and Y are independent,} \\ &p(X,Y) = p(X) * p(Y) \end{split}$$

$$T$$
 (X,Y)

Therefore,
$$E_{X,Y}(log \frac{p(X,Y)}{p(X)p(Y))} = E_{X,Y}(log \frac{p(X)p(Y)}{p(X)p(Y)})$$

$$= E_{X,Y}(log(1)) = 0$$

3.2 2

Using Jensen's Inequality, we can show KL Divergence $D_{KL}(p\|q) \geq 0$, and it meets equality (= 0) if and only if $p(x) = q(x), \forall x$ which means p and q have exactly same density function.

Jensen's Inequality has equality condition if and only if inner function (log in I(X;Y)) is affine function or variable(P(X,Y)/P(X)P(Y)) in I(X;Y)) is constant. Therefore, for KL Divergence to be 0, P(X,Y)/P(X)P(Y) should be constant, exactly "1" as pdf <= 1,

Thus
$$I(X;Y) = D_{KL}(p(X,Y)||p(X)p(Y)) = 0 - > p(X,Y) = p(X)p(Y).$$

Homework #(HW7) Seo Junwon

Therefore X and Y are Independent.

4 Entropy of a multivariate normal distribution

$$\begin{split} &H(x) = -\int p(x) * log(\frac{e^{-0.5(x-\mu)^T \Sigma^{-1}(x-\mu)}}{2\pi^{n/2} det(\Sigma)^{0.5}}) dx \\ &= -\int p(x) * log(e^{-0.5(x-\mu)^T \Sigma^{-1}(x-\mu)}) dx + \int p(x) * log(2\pi^{n/2} det(\Sigma)^{0.5}) dx \\ &\text{Using trace trick,} \\ &= 0.5 * \int p(x) * (x-\mu)^T \Sigma^{-1}(x-\mu) dx + log(2\pi^{n/2} det(\Sigma)^{0.5}) dx \\ &= 0.5 * \int p(x) * tr((x-\mu)^T \Sigma^{-1}(x-\mu)) dx + \frac{N}{2} log(2\pi) + \frac{1}{2} log(det(\Sigma)) \\ &= 0.5 * tr(\int \Sigma^{-1} p(x)(x-\mu)(x-\mu)^T) dx + \frac{N}{2} log(2\pi) + \frac{1}{2} log(det(\Sigma)) \\ &= 0.5 * tr(\Sigma^{-1} \Sigma) + \frac{N}{2} log(2\pi) + \frac{1}{2} log(det(\Sigma)) \\ &= \frac{N}{2} + \frac{N}{2} log(2\pi) + \frac{1}{2} log(det(\Sigma)) \end{split}$$
